Center for International Climate and Environmental Research - Oslo (CICERO), Norway; j.s.fuglestad@cicero.uio.no, glen.peters@cicero.uio.no

What is new in version V1.1 versus V1.0?

Land use and non-CO₂ forcing should be included:

- a) Preferred option in simulation #1 to #3 is to include non-CO₂ radiative forcings to the extent possible. Non-CO₂ forcing should be kept constant after 2010.
Reason: several Earth System Model (ESM) groups will use an existing simulation over the industrial period with all forcings included as a starting point for simulations #1 to #3.
- b) Preferred option in simulation #1 to #3 is to include land use in the simulations. Land use area should be kept constant after 2010.
Reasons: see above; in addition, uptake of CO₂ on natural land is different compared to uptake on agricultural land within a grid cell. This will affect results.

Clarifications:

- c) The CO₂ concentration should be preferentially increased instantaneously by 47.1032 ppm in all atmospheric grid cells at the beginning of year 2015 in simulation #3 and in models that include an atmospheric transport scheme.
- d) If a group is sure that CO₂ remains at a constant value with the emissions diagnosed in run #1, run #2 may be skipped. This may only apply to ESMs and it remains recommended to perform run #2 to avoid problems with model drift.
Reason: For ESM models, CPU time may be an issue and run #2 is for control purposes only.
- e) It is assumed that group will store more output individually than just the few global numbers that we ask for as output. It is anticipated that the runs may be very useful to diagnose response patterns for a wide range of variables. In additions to IRFs for CO₂, temp, and sea level, one may also want to analyze pH, precip, etc.

Impulse response function of climate-carbon cycle models: a model intercomparison study

Protocol V1.1

Documents and updates are available online: http://www.climate.unibe.ch/~joos/IRF_Intercomparison

Global warming potentials (GWP) of different gases are used as a metric to compare emissions of various greenhouse gases in the Kyoto Basket approach. The response in atmospheric CO₂ to an instantaneous release of carbon into the atmosphere, the atmospheric CO₂ impulse response function (IRF), is used for the computation of global warming potentials (GWP) and global temperature change potential (GTP) (Shine et al., 2005).

The goal of this exercise is to determine the atmospheric CO₂ impulse response function (IRF) by a suite of carbon-cycle climate models to explore model-model differences. Results will be written up for publication in a peer-reviewed journal in spring 2012 (IPCC AR5 WG1 deadline is summer 2012) in order to be available for calculations of GWPs in IPCC AR5. The results will also be useful for metrics and simplified climate models in other contexts.

Model requirements

The model must be able to compute the redistribution of anthropogenic carbon among the principal carbon reservoirs atmosphere, land biosphere, and ocean. Further compartments such as ocean sediments may also be included. Preferentially, the model simulates changes in climate in response to CO₂ radiative forcing and includes a representation of the relevant carbon cycle-climate feedbacks.

Model runs: overview

The scenario setup is inspired by the calculation of the IRF function as done for the Second Assessment Report (SAR) and as used in the Kyoto GWP with the Bern SAR model version and as repeated in preparation of the Fourth Assessment. The setup relies on that described in Enting, Wigley, Heimann, CSIRO Division of Atmospheric Research. Technical Paper No 31, 1994:

Three simulations are performed:

- (a) The model is forced with historical concentration up to a reference year (here $t_{ref}=2010$) and then concentration are kept fixed thereafter at a constant value (here $CO_{2,ref}=389$ ppm). The allowed emission are calculated from the change in total inventory (prescribed atmospheric change plus modelled ocean and terrestrial uptake)
- (b) A simulation with prescribed emissions from (a)
(or concentration prescribed up to the reference year and emissions prescribed thereafter)
- (c) same as (b) but an impulse of carbon, here of 100 GtC, added instantaneously to the atmosphere five years after the reference year (here in 2015).

The normalised IRF is then approximately:

$$\text{IRF}(t=t_{\text{model}}-2015.0) = (\text{CO}_2(t_{\text{model}})-\text{CO}_{2,\text{ref}})/(100 \text{ GtC}/2.123\text{GtC/ppm}) \quad \text{for } t_{\text{model}} > 2015$$

Model runs: detailed description

A) CO₂ background concentration of 389 ppm

1. PresCO2_389ppm: The simulation starts from preindustrial conditions. Atmospheric CO₂ is prescribed and compatible emissions (=change in all carbon reservoirs) diagnosed. Atmospheric CO₂ is prescribed to follow the historical evolution up to year 2010. After 2010, the concentration is kept fixed at the value of 389.0 ppm. The diagnosed emissions should be written frequently (at least annually); these will be used to drive the model in run 2 and 3. An input file with the historical concentrations is provided (file name: co2ccn_irf_850_2010_v1.0.dat).
A restart file may be written in 2010 to start simulation 2 and 3 in 2010
2. PresEmiss_389ppm: run 2 may either start in 2010 as a continuation of run 1 or at the same preindustrial initial conditions used in run 1. Atmospheric CO₂ is evolving freely. Diagnosed emissions from run PresCO2_389ppm are used to force the model. (Expected result: the computed CO₂ evolution should be close to the evolution prescribed in run PresCO2_389ppm, see Figure 1).
3. PresEmiss100_389ppm: Atmospheric CO₂ is evolving freely. Diagnosed emissions from run PresCO2_389ppm are used to force the model as in run PresEmiss_389ppm. In addition, 100 GtC are released at the beginning of year 2015. (Expected results: Atmospheric CO₂ will increase by 47.1032 ppm above the background concentration (~389 ppm) in 2015 and then slowly decline over the coming decades, see Figure 1)

Remarks:

- It is crucial that the carbon pulse will be added to a constant background concentration of 389 ppm for comparability (roughly 2010 value).
- run 1 (PresCO2_389ppm): An existing run or setup from the CMIP or EMIC Intercomparison projects may be used up to a concentration of 389 ppm.
- run 3 (PresEmiss100_389ppm): The atmospheric CO₂ concentration should be increased at the beginning of year 2015 by 47.1032 ppm (100 GtC/2.123 GtC/ppm) in all atmospheric grid cells.
- non-CO₂ forcing agents should be included to the extent possible. Non-CO₂ forcing should be kept constant at 2010 level after 2010 (or at the year at which 389 ppm CO₂ is reached).
- land use and land use changes should be included to the extent possible. Land use area should be kept constant at 2010 level after 2010.
- If CPU time is an issue and if a group is sure that CO₂ remains at a constant value with the emissions diagnosed in run #1, run#2 may be skipped. This may only apply to ESMs and it is strongly recommended to perform run #2 to avoid problems with model drift.

B) Preindustrial Set

Runs 4 to 5 start from preindustrial conditions

4. CTRL: Control simulation with constant boundary conditions and freely evolving atm. CO₂
5. PI100: Freely evolving atm. CO₂. 100 GtC are released into the atmosphere during year 10 of the control simulation and then continued. (Expected result: atm CO₂ will increase from the preindustrial value of around 280 ppm by about 45 ppm to 325 ppm in year 10. Afterwards, the CO₂ concentration will then decrease due to uptake by the ocean and the land biosphere).
6. PI5000: as PI100, but 5000 GtC are released instead of 100 GtC

Remark: an available control simulation may be used to minimize work

Resulting IRFs

We will use your results to compute impulse response functions for CO₂ and other variables:

- a) IRF_100GtC_389ppm: The difference in atm. CO₂ of run PresEmiss100_389ppm and PresEmiss_389ppm divided by the pulse size of 47 ppm will yield the (normalized) IRF for a background concentration of 389 ppm and a pulse size of 100 GtC (see Figure 2)
- b) IRF_100GtC_PI: The difference in atm. CO₂ of run PI100 and CTRL will yield the IRF for preindustrial background conditions and a pulse size of 100 GtC
- c) IRF_5000GtC_PI: The difference in atm. CO₂ of run PI5000 and CTRL will yield the IRF for preindustrial background conditions and a pulse size of 5000 GtC

Duration of runs

Preferentially, simulations are run for 2000 years after the pulse release until a complete equilibrium between atmosphere-ocean-land biosphere is re-established. If this is not feasible, runs of shorter duration are also welcome. Usually models are close to equilibrium after 1000 years. Global Warming Potentials for which the IRFs will be used were tabulated in past IPCC reports for 500, 100, and 20 years. A time horizon of 100 years is used in the Kyoto protocol.

A minimum of 100 years after the pulse release is requested.

Models that include ocean sediments and/or weathering and that are cost-efficient enough may also be run over many millennia (e.g. 100 ka).

Priority of runs

The *top priority* is to get results needed to compute the IRF for a background concentration of 389 ppm (IRF_100GtC_389ppm). For this, *runs 1, 2, and 3* are required.

Alternative: If computing requirements are too high for run 1 to 3, please provide at least results for runs 4 and 5 (PI100, CTRL).

Conversion factor GtC to ppm

Please use a conversion factor of 2.123 GtC per ppm

Preindustrial condition

It is up to the researcher to define the exact preindustrial state and the exact evolution how to reach the 2010 atmospheric CO₂ value of 389 ppm. However, model runs should start before 1900 AD and concentration should be kept fixed at a value of 389 ppm a few years before and during the pulse release. The idea is that the carbon pulse is added for the same background concentration of 389 ppm in all models.

Other forcings

Non-CO₂ forcings and land use are preferentially included in run 1 to 3; keep non-CO₂ forcing and land use area constant after 2010 at the level of year 2010. A suitable set of forcing is provided by the EMIC Intercomparison Project (<http://climate.uvic.ca/EMICAR5/forcing>).

Output

Ascii files with global mean values, provide at least 5 significant digits for each run.

- a) File name: RUNNAME_MODELNAME_Modelversion_startyear_endyear.dat, e.g. "PresCO₂_2010_Bern3DLPX_v1.0_1750_4015.dat" for run 1 with the Bern3DLPX model, version 1.0 and simulation starting at 1750 AD and ending at 4015
- b) Header:
 - start each comment line with: #
 - indicate run name
 - provide contact address,
 - indicate model name and version and model components included,
 - indicate climate sensitivity of model
 - conversion factor used to convert GtC into ppm and/or pulse size in ppm
 - description of non-CO₂ forcing applied
 - indicate whether tabulated data show annual averages or instantaneous values
 - column headers with units
- c) Tabulated data including year, global mean values of atmospheric CO₂ in ppm (CO₂atm), global mean net air-to-sea carbon flux in GtC per year (F_{as,net}), global mean net air-to-land carbon flux in GtC per year (F_{ab,net}), global mean surface temperature in Celsius (T), global mean sea level rise in cm (SLR), ocean heat content in Joule (Heat)

```
# year CO2atm [ppm] Fas,net [GtC/yr] Fab,net [GtC/yr] T [deg Celsius] SLR[cm] Heat[J]
```

A text file in ascii describing the model, model resolution, model components, climate sensitivity, and appropriate references. File name: MODELNAME_Modelversion_description.txt. Include contact address.

It is assumed that group will store more output individually than just the few global numbers that we ask for as output. It is anticipated that the runs may be very useful to diagnose response patterns for a wide range of variables. In additions to IRFs for CO₂, temp, and sea level, one may also want to analyze pH, precip, etc.

Deadlines

Please let us know by *15 December 2011* whether you plan to contribute and submit the runs until **15 February 2012** to joos@climate.unibe.ch and roth@climate.unibe.ch

Results obtained with the Bern3D-LPX model for a CO₂ background of 389 ppm (R. Roth)

Figure 1: Simulated evolution of atmospheric CO₂ for runs 2 and 3 (PresEmiss_389ppm PresEmiss100_389ppm). 100 GtC are instantaneously released at the beginning of year 2015 in simulations PresEmiss100_389ppm (red) in addition to the emissions prescribed in run PresEmiss_389ppm (black). Prescribed emissions were diagnosed from a run in which atmospheric CO₂ was prescribed to follow the observed evolution until 2010 and kept constant at 389 ppm after 2010.

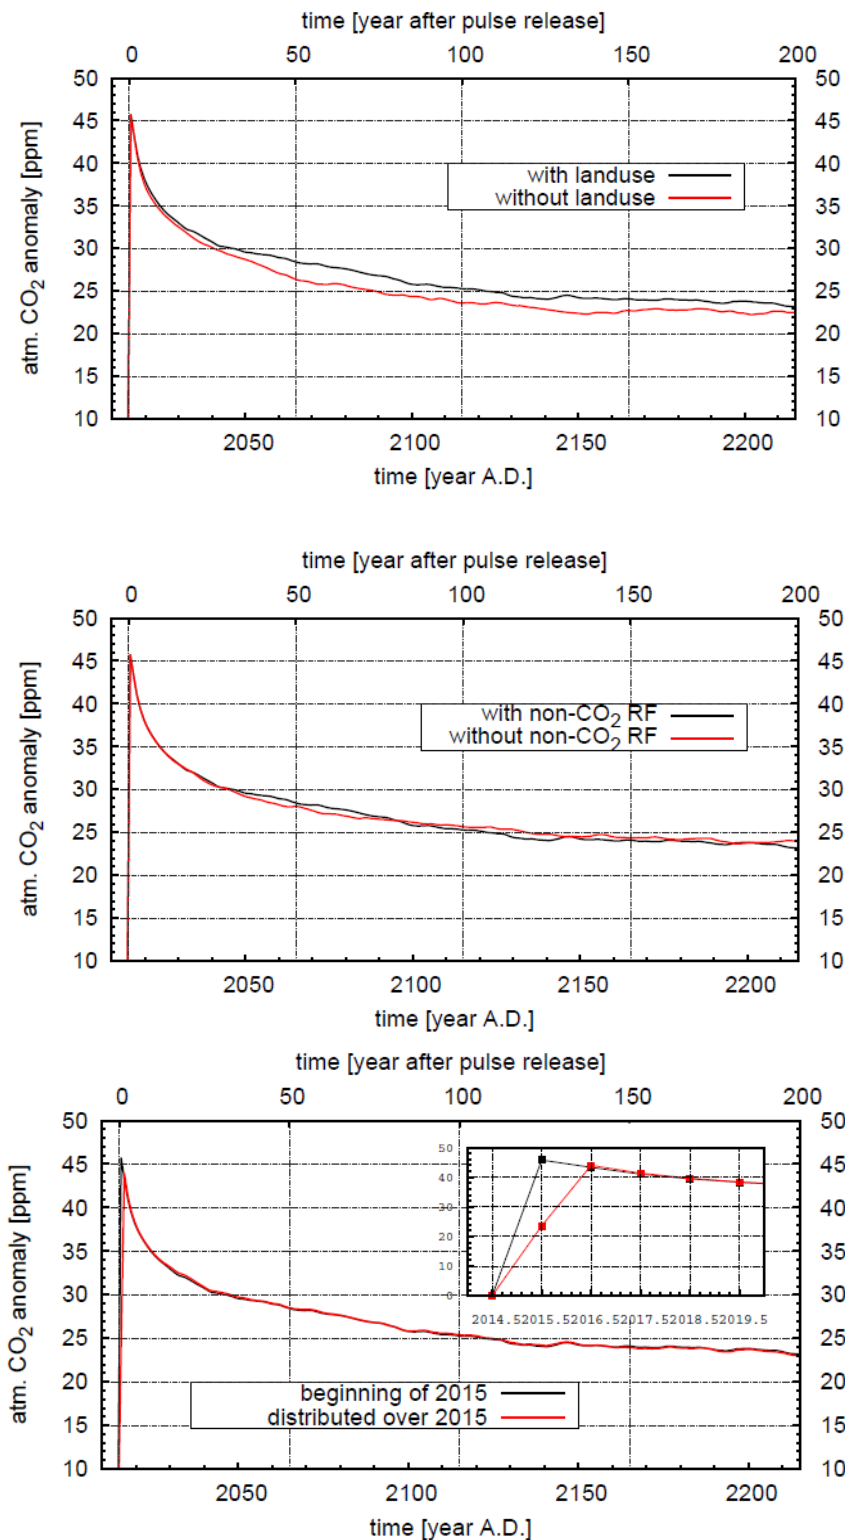

Figure 2: CO₂ impulse response function (IRF) as obtained from the difference of the runs shown in figure 1. The IRF is normalised by the size of the pulse input. Time is shifted such that year 0 corresponds to the time when the pulse of 100 GtC was released into the atmosphere.

Results of sensitivity runs with the Bern3D-LPX model (Raphael Roth)

Differences in Impulse Response Function computed with the Bern3D-LPX model for different model setups. Top: Results from simulations with and without anthropogenic land use. Middle: Results from simulations with and without non-CO₂ forcings. Bottom: release of pulse emissions at the beginning of the year versus a release of 100 GtC over one year. Note that the Bern3D-LPX model considers CO₂ to be well mixed in the atmosphere. Thus differences in IRF may be larger for models that feature atmospheric carbon transport.
